(54) Title: NONAQUEOUS ELECTROLYTE

BEST AVAILABLE COPY

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Propylene Carbonate @ .51 moles/l

VO 2004/062007 A1

(57) Abstract: A non-aqueous electrolyte comprising a pyridinium-based salt in a non-aqueous solvent at a concentration less than

Express Mail Label No. EV399609393US

NONAQUEOUS ELECTROLYTE**10/547241****REFERENCE TO RELATED APPLICATIONS**

This application claims priority to US Provisional application No. 60/437,321, filed December 31, 2002, and hereby incorporated by reference.

FIELD OF INVENTION

The present invention relates generally to non-aqueous electrolytes, and, more specifically, to non-aqueous electrolytes for use in supercapacitors.

BACKGROUND OF INVENTION

Significant effort has been invested over the years in improving the energy and power of electrical energy storage devices such as capacitors and batteries. Of particular interest herein are supercapacitors. These energy storage devices are particularly useful in short term, high-energy applications such as powering electric vehicles or cellular communication. A typical supercapacitor comprises carbon-based electrodes and an electrolyte having charged ions which can be ordered about the electrodes to create a potential between the electrodes. Therefore, critical to the overall performance of a supercapacitor is its electrolyte.

An electrolyte typically comprises an ionic salt dissolved in a solvent. A wide variety of solvents and salts are available for such use, offering specific advantages depending on the application being considered (e.g., low temperature vs. high temperature). Generally, non-aqueous electrolytes are preferred from the standpoint of electrochemical stability and are considered herein in detail. A common non-aqueous electrolyte comprises a salt, e.g., tetraethyl ammonium tetrafluoroborate (TEABF₄), dissolved in an organic solvent, e.g., acetonitrile (AN), propylene carbonate (PC) or gamma butyrolactone (GBL). Generally, the conductivity of the electrolyte depends upon its concentration of salt. Unfortunately, the conductivity of non-aqueous electrolytes tends to be limited by the solubility of the salt in the solvent.

A new non-aqueous electrolyte system disclosed in US Patent No. 5,965,054 purportedly addresses this problem by identifying a class of salts which are highly soluble in non-aqueous solvents to provide good conductivity. More specifically, the '054 patent discloses a salt

consisting of a cation selected from a number of an alkyl substituted, cyclic delocalized aromatics and their perfluoro derivatives, and a polyatomic perfluorinated anion. Among a number of alkyl substituted, cyclic delocalized aromatics disclosed, the '054 patent states that imidazolium, particularly, 1-ethyl-3 methyl imidazolium (EMI) and 1-methyl-3 methyl imidazolium (MMI) in combination with PF₆ are preferred because they are particularly soluble and thus can be added in relatively high concentration to a non-aqueous solvent. It is claimed that this high concentration of salt in the non-aqueous solvent correlates to high conductivity.

Although the above-mentioned electrolytes have desirable electrochemical properties that make them suitable for electrolytes, they are, unfortunately, expensive. Therefore, there is a need for a less expensive non-aqueous electrolyte having performance which is at least as good as known electrolytes. The present invention fulfills this need among others.

SUMMARY OF INVENTION

The present invention provides for a relatively inexpensive non-aqueous pyridinium-based electrolyte having electrochemical performance comparable or better than conventional electrolyte systems, even at relatively low concentrations. Specifically, it has been discovered that a salt consisting of a cation of pyridinium (PyH) and an anion of a fluorinated non-metal, such as tetrafluoroborate (BF₄⁻), can be dissolved in certain known solvents such as, propylene carbonate (PC), acetonitrile (AN), and gamma butyrolactone (GBL), to yield an electrolyte having an unexpectedly wide window of electrochemical stability and unexpectedly high conductivity, even at relatively low concentrations.

Although the use of pyridinium as a cation has been disclosed among a host of other alkyl substituted, cyclic delocalized aromatics in US Patent No. 5,965,054, it was never considered individually and its excellent electrochemical performance at relatively low concentrations and its lower cost as compared to the other disclosed alkyl substituted, cyclic delocalized aromatics were not recognized. *To the contrary*, the '054 patent exalts the use of the more expensive 1-ethyl-3 methyl imidazolium (EMI) and 1-methyl-3 methyl imidazolium (MMI) cations over pyridinium primarily due to their high solubility. That is, the '054 patent states that EMI and MMI are particularly soluble and thus can be used in higher concentrations in electrolytes, i.e.,

over 2M and even greater than 3M. Since they can be used in higher concentrations, the '054 patent purports that they impart greater conductivity to the electrolyte.

The applicants have discovered, however, that pyridinium has excellent electrochemical properties even at relatively low concentrations. Specifically, the pyridinium cation and a fluorinated anion, such as BF₄⁻, form a salt which has unexpectedly good conductivity and electrochemical stability at concentrations below 2M. Therefore, the present invention provides for an effective electrolyte salt which is not only relatively inexpensive, but which can also be used in relatively low concentrations. Since less of the inexpensive pyridinium-based salt can be used with satisfactory results, there is a two-fold savings realized by its use. This is a significant and unexpected advantage over conventional and newly introduced non-aqueous salts.

Accordingly, one aspect of the present invention is an electrolyte comprising a pyridinium-based salt at a relatively low concentration. In a preferred embodiment, the electrolyte comprises a salt of pyridinium and a fluorinated anion at a concentration of less than about 2M in a non-aqueous solvent. Preferably, the solvent is an organic solvent, such as a linear ether, cyclic ether, ester, carbonate, formate, lactone, nitrile, dinitrile, amide, sulfone or sulfolane, and, more preferably, an alkyl carbonate, alkyl nitrile or alkyl lactone. In a particularly preferred embodiment, the solvent is propylene carbonate (PC), acetonitrile (AN), or gamma butyrolactone (GBL).

The non-aqueous electrolytes of the present invention may be used in any traditional device or apparatus using an electrolyte. Of particular interest herein is their use in electrical energy storage devices, especially electrochemical capacitors/supercapacitors. The electrolytes can also be used in potentiometric and voltammetric electrochemical sensors, photovoltaic devices, fuel cells, and in primary and secondary batteries employing alkali and alkaline earth anode materials so long as the electrolyte contains the cation of the alkali or alkaline earth anode material. Further, the electrolytes of the invention may be used as media for catalysis or electrocatalysis.

Accordingly, another aspect of the present invention is a device containing a pyridinium-based electrolyte. In a preferred embodiment, the device is an energy storage device, and, more

preferably, a supercapacitor having carbon-based electrode and an electrolyte comprising a pyridinium-based salt at a concentration of less than about 2M in a non-aqueous solvent.

BRIEF DESCRIPTION OF DRAWINGS

Other features and advantages of the invention will be apparent from the following detailed description of the invention, taken in conjunction with the accompanying drawings in which:

Figs. 1-3 show the electrochemical stability for various concentrations of PyHBF₄ in PC;

Figs. 4-7 show the electrochemical stability for various concentrations of PyHBF₄ in AN; and

Figs. 8 & 9 show the electrochemical stability for various concentrations of PyHBF₄ in GBL.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The non-aqueous electrolytes of the invention are superior to conventional electrolytes in a number of respects that serve to make them particularly useful in electrical energy storage devices. Specifically, we have determined that pyridinium (PyH⁺) based salts can be dissolved in an organic solvent to provide an electrolyte having excellent electrochemical properties. Such electrolytes can be used in a host of electrochemical applications and are particularly useful in carbon-based electrode supercapacitors.

The salt of the present invention comprises the cation pyridinium and an anion. The ions are selected to complement one another such that when the ionic compound is dissolved in an organic solvent, the ions readily dissociate and have good mobility in the organic solvent to align with their respective electrodes. To this end, the ions are small enough to promote mobility through the solvent, but are not so small as to be solvated excessively to become, in effect, larger compounds with compromised mobility. With these criteria in mind, the cation pyridinium in combination with a perfluorinated non-metal anion is preferred. Preferred non-metal ions include boron, phosphorous, sulfur, arsenic and antimony. Alternatively, the anion may be selected from the group consisting of perfluoroalkylborates, perfluoroalkylphosphates, perfluoroalkylsulfonates ($C_nF_{2n+1}SO_3^-$, with n=0, 1, 4, 6, 8), perfluoroalkyl-substituted imides, in particular bis(trifluoromethylsulfonyl) imide (prepared, for example, in accordance with U.S. Patent No. 45,054,997), and perfluoroalkyl-substituted methanides, in particular

tris(trifluoromethylsulfonyl)methanide (prepared, for example, in accordance with U.S. Patent No. 5,273,840). More preferably, the anion comprises tetrafluoroborate (BF₄⁻).

The cation pyridinium in combination with the anion tetrafluoroborate was found to have unexpectedly good ionic properties including excellent mobility, conductivity and electrochemical stability. Furthermore, given the relatively low cost of pyridinium, the PyHBF₄ salt is substantially less expensive than traditional salts such as tetraethyl ammonium tetrafluoroborate and EMIPF₆.

Pyridinium tetrafluoroborate is a known material and can be prepared very economically using known techniques. For example, it can be prepared using the procedures and techniques disclosed in (Polyhedron Vol. 4, pp 787-789 (1985)). The pyridinium tetrafluoroborate should be relatively pure, preferably high purity grade with low water and oxygen content (<30 ppm). It is important that water and oxygen impurities be minimized as they have a particularly detrimental effect on the electrochemical performance of the salt.

Although PyHBF₄ is the preferred salt in the electrolyte of the present invention, it may be preferable to augment the electrolyte with a conventional conductive salt, e.g., tetraalkylammonium or tetraalkylphosphonium salt, to customize it for a particular application.

Since an electrolyte is a system of ions in a solvent, the solvent is important and affects directly the performance of the electrolyte. Preferably, the non-aqueous solvent is an organic solvent. More preferably, the organic solvent is a linear ether, cyclic ether, ester, carbonate, formate, lactone, nitrile, dinitrile, amide, sulfone or sulfolane, and, even more preferably, is an alkyl carbonate, alkyl nitrile or alkyl lactone. In a particularly preferred embodiment, the solvent is propylene carbonate (PC), acetonitrile (AN), or gamma butyrolactone (GBL).

It may be preferable to use a combination of PC, AN and GBL for a particular application. Likewise, it may be preferable to use a combination of two or more non-aqueous solvents mentioned in the paragraph above for a particular application.

Suitable electrolytes must have high conductivity and good electrochemical stability.

The power output capability of an energy storage device depends on the working voltage and the maximum current output capability of the electrolyte in combination with the electrodes. The 5 working voltage is directly related to the electrolyte's electrochemical stability while the maximum current output (at least in the double layer type supercapacitors) is mainly dictated by the electrolyte's conductivity.

To evaluate an electrolyte's electrochemical stability, the electrolyte is subjected to cyclic voltammetry to determine its "voltage window." As used herein, the term "voltage window" 10 refers to the voltage range which the electrolyte can tolerate without substantially reacting (i.e., undergoing reduction or oxidation). To determine the voltage window, an electrolyte is placed in a cell having a working electrode, a counter electrode, and a test electrode, which is immediately adjacent but not touching the working electrode. The electrodes in the cell are connected to a 15 cyclic voltammetry apparatus, called a potentiostat, which is configured to adjust the current between the working and counter electrodes to maintain a "desired voltage" between the working electrode and the reference electrode. The voltage between the reference electrode and the working electrode can be varied as a function of time in a programmed manner (for example, suitable results have been obtained using a linear change rate of 20 mV/s). The voltage window 20 is determined by progressively increasing the desired voltage (in both the positive and negative directions) until there is a precipitous increase in the current required to drive the working and counter electrodes to maintain the desired voltage. The sharp rise in current at the end voltages generally indicates the breakdown voltage of the electrolyte, meaning that the salt or the solvent 25 is undergoing a reduction reaction at the negative end voltage or an oxidation reaction at the positive end voltage. Such reactions could include gas evolution or simple oxidation/reduction reactions. The voltage difference between these two end voltages at which the current reaches a predetermined value, for example 100 mA/cm², is called the electrochemical window or "voltage window."

The voltage window of pyridinium-based electrolytes is considerably higher than one would expect. For example, an electrolyte of PyHBF₄ in PC at a concentration of 1.02M has a voltage window of 4 volts, an electrolyte of PyHBF₄ in AN at a concentration of 0.59 M solution has a voltage window of 3.5 V, and an electrolyte of PyHBF₄ in GBL at a concentration of 5 1.62M solution has a voltage window of 4 volts. The voltage window of 4 V for PyHBF₄ in PC and GBL is higher than that of conventional electrolyte systems and provides high power capability for supercapacitor applications. Furthermore, the voltage window for all three solvents is generally constant for different pyridinium concentrations. Such constant stability across a range of salt concentrations is advantageous. Accordingly, the electrolyte of the present 10 invention has a voltage window preferably of at least 3.5 V and, more preferably, of at least 3.8V.

The conductivity for pyridinium-based electrolytes is comparable to prior art electrolyte systems, and is particularly good for PyHBF₄ in AN and GBL, even at low concentrations. For example, an electrolyte of PyHBF₄ in PC at a concentration of 1.02M solution has a conductivity 15 of 10.53 mS/cm, an electrolyte of PyHBF₄ in AN at a concentration of 0.59 M solution has a conductivity of 32 mS/cm, and an electrolyte of PyHBF₄ in GBL at a concentration of 1.62m/l has a conductivity of 20.2 mS/cm. By way of comparison, EMIPF₆/PC has a maximum conductivity of 15.3 mS/cm at 2M concentration ('054 patent, Table 2), and the maximum conductivity for 1M TEABF₄/PC is 13 mS/cm (Ue et al., J. Electrochem. Soc. 141:2989, 1994). 20 The conductivities of the pyridinium-based electrolytes compare favorably with these electrolyte systems, and, the PyHBF₄/AN and PyHBF₄/GBL systems, in particular, compare favorably with these maximum conductivities of conventional electrolytes, even at lower concentrations.

The concentration of the PyHBF₄ in the solvent can be tailored to the application's 25 particular needs. The preferred concentration of the electrolyte for the supercapacitor application is one at which the conductivity and the electrochemical window are maximum. Since the voltage window is generally constant for the various concentrations, optimization will typically be a function of optimizing conductivity. Furthermore, since the high surface area activated carbon electrodes are standard for non-aqueous systems, the power output capability depends mainly on the electrolyte conductivity. Higher electrolyte conductivity leads to lower internal 30 voltage drop in the capacitor. Generally, increasing the concentration of the salt in the solvent

will improve the electrolyte's conductivity which, in turn, improves its performance as an electrolyte. Accordingly, if the objective is to maximize conductivity, it is preferable to saturate the electrolyte composition with salt. However, if a particular conductivity can be met using a lower concentration of salt, cost considerations would dictate using sub-saturation levels of salt.

5 Generally, it is preferred that the concentration of pyridinium-based salt be less than 2M. More preferably, the concentration is less than 1.75M and, still more preferably, around 1.0M. With respect to PC, it has been found that suitable results have been obtained with a concentration of PyHBF₄ below 1.02 M. With respect to AN, suitable results have been obtained with a concentration of PyHBF₄ of less than 1.1M. With respect to GBL, suitable results have been obtained with a concentration of PyHBF₄ less than about 1.62 M.

10

The excellent electrochemical performance and the relatively low cost of pyridinium-based electrolytes make them ideal for use in electrolyte systems in batteries and capacitors, including single cell and multi-cell capacitor devices, and other non-aqueous electrochemical capacitors, such as the Type III redox polymer system (Ren et al. Electrochemical Capacitors, 15 F.M. Delnick and M. Tomkiewicy, Editors, PV95-29, p.15, The Electrochemical Society Proceedings Services, Pennington, N.J. (1996); Arbizzani et al., Adv. Mater. 8: 331, 1996).

The examples below are provided to illustrate the invention and should not be construed as limiting the invention to the particular embodiments disclosed therein.

Example 1

20 Solutions of varying concentrations of PyHBF₄ in PC were prepared by mixing high purity propylene carbonate solvent (Honeywell's high purity PC used in Digirena® electrolyte) and high purity PyHBF₄ (Sigma Aldrich Co.). The PyHBF₄ was transferred from its sealed original container to a glove box. The moisture level and the oxygen level in the glove box was maintained below 1 and 2 ppm, respectively. Such limitations are preferred, however, moisture and oxygen levels below 10 ppm may be adequate. In preparing a saturated electrolyte solution, 25 a known quantity of the high purity propylene carbonate solvent was transferred to a glass container with a cap or lid. A known amount of pyridinium tetrafluoroborate was added to the container and mixed until all of the added quantity of the solid salt was dissolved. To facilitate dissolution, a magnetic stirrer bar is placed inside the solution and stirred well by placing it on a

magnetic stirrer. After the salt is dissolved, another small known quantity of the salt was added and the procedure was repeated until trace amounts of undissolved salt were visible. The amount of the salt and the solvent were used to calculate the solubility of the salt in propylene carbonate. This is the highest concentration solution indicated in Table 1. Solutions of varying concentrations other than saturated were prepared by dissolving the required amount of the salt in the required amount of the solvent. It can also be prepared by diluting the saturated solution with the required amount of the solvent. These less-than-saturated solutions are also listed on Table 1.

Each concentration above was subjected to cyclic voltammetry to determine its voltage window. The voltage window was determined using an electrochemical microcell. The 10 microcell comprised electrodes mounted to its top. Specifically, a 3mm diameter polished glassy carbon rod was used as a working electrode. This rod was covered on the cylindrical surface with a plastic sheath. A silver wire was used as a reference electrode. The tip of the silver wire is placed as close to the working electrode as possible without touching it (i.e., approximately 15 1mm). A platinum foil was used as a counter electrode. The electrodes are connected to an EG&G Princeton Applied Research Corp M273A Potentiostat. The operation of the potentiostat was controlled by a desktop/personal computer using PARC M270 Research Electrochemical software.

In determining the voltage window for each concentration, approximately 15 ml of 20 solution of each concentration was transferred to the microcell described above and an initial voltage was measured. This is known as rest potential or open circuit potential. The current was substantially zero at this time. Then the voltage between the working electrode and the reference electrode is continuously cycled between a positive voltage limit and a negative voltage limit by changing the voltage at a constant rate. The voltage changes from the rest potential to one 25 voltage limit, then to the other voltage limit and finally ending at the rest potential where it started. The current that flows between the working electrode and the counter electrode in response to the above voltage change was measured. The voltage-current data is plotted in graphical form and is called a cyclic voltammogram.

The graph produced by this technique for the PyHBF₄/PC electrolyte solution is 30 presented in Figs. 1 - 3 for various concentrations up to the saturation limit of 1.02 M.

Generally, the presence of a current peak on the top half or the bottom half of the graph indicates respectively an electrochemical reduction or oxidation process taking place at the potential corresponding to the peak location. In this electrolyte and electrode system there is no oxidation or reduction peak. It means that this electrolyte is stable through the voltage window indicated by the sharp rise in the current level at the end voltages. In this case we see an electrochemical window of nearly 4 V. This is comparable to or higher than any known state of the art electrolyte system.

The conductivity of each solution was measured using a VWR NIST-Traceable conductivity meter. The conductivity as a function of the electrolyte concentration is shown in Table 1.

Table 1

Initial rest potential of the PyHBF₄/PC electrolyte solutions and their conductivity

Concentration (M)	Rest Potential (V)	Conductivity (mS/cm)	Voltage Window (V)
0.25	0.277	4.5	4.00
0.38	0.317	5.9	4.00
0.51	0.278	7.2	4.00
0.75	0.424	9.1	4.00
1.02	0.563	10.5	3.90

Thus, the figures and the table provide evidence to the electrochemical performance of this electrolyte at different concentrations. Even at relatively low concentrations, for example, below 1M, the electrochemical performance of the pyridinium-based salt is relatively good compared to prior art. Generally, the preferred concentration of the electrolyte for the supercapacitor application is one at which the conductivity and the electrochemical voltage window are maximum. Since the voltage window remains fairly constant at all concentrations, selecting a preferred concentration becomes a function of desired conductivity. Higher concentrations equate to higher conductivities.

Example 2

Solutions of varying concentrations of PyHBF₄ in acetonitrile were prepared by mixing high purity acetonitrile solvent (Honeywell's high purity acetonitrile used in Digirena® electrolyte) and high purity PyHBF₄ (supplied by Sigma Aldrich Co,) in the same way was discussed above with respect to Example 1.

The voltage window was determined using the same apparatus and procedure as described above with respect to Example 1. The graph produced by this technique is presented in Figures 4-7 for the concentrations 0.33 m/l and 0.22 m/l of pyridinium tetrafluoroborate in acetonitrile. Generally there will be current peaks on the top half or the bottom half of the graph if there are electrochemical reduction or oxidation processes occurring at any potential in this voltage window. In the PyHBF₄/AN case there are no such electrochemical reactions observed other than at the end voltages. In this case we see an electrochemical window of 3.5 V as shown in Table 2. This is comparable to or higher than the state of the art electrolyte, tetraethyl ammonium tetrafluoroborate/acetonitrile (TEABF₄/AN).

The conductivity of each solution was measured in the same manner as described in Example 1. The conductivity as a function of the electrolyte concentration is shown in Table 2. Thus, the figures and the table provide evidence to this capability of the herein disclosed new electrolyte.

Table 2

Initial rest potential of the PyHBF₄/AN electrolyte solutions and their conductivity

Concentration (M)	Rest Potential (V)	Conductivity (mS/cm)	Voltage Window (V)
0.22	0.42	7.27	3.55
0.33	0.394	22.5	3.85
0.46	0.383	28.2	3.85
0.59	0.264	31.9	3.75
0.75	0.330	35.1	3.85
1.00	0.275	41.04	3.90
1.14	0.245	51.56	3.90

Thus, the figures and the table provide evidence to the electrochemical performance of this electrolyte at different concentrations. Even at relatively low concentrations, for example,

below 1M, the electrochemical performance of the pyridinium-based salt is relatively good compared to prior art. Generally, the preferred concentration of the electrolyte for the supercapacitor application is one at which the conductivity and the electrochemical voltage window are maximum. Since the voltage window remains fairly constant at all concentrations, 5 selecting a preferred concentration becomes a function of desired conductivity. Higher concentrations equate to higher conductivities.

Example 3

Solutions of varying concentrations of PyHBF₄ in gamma butyrolactone solvent were prepared by mixing high purity gamma butyrolactone solvent (Honeywell's high purity gamma 10 butyrolactone solvent used in Digirena® electrolyte) and high purity PyHBF₄ (supplied by Sigma Aldrich Co,) in the same way was discussed above with respect to Example 1.

The voltage window was determined using the same apparatus and procedure as described above with respect to Example 1. The graph produced by this technique for the PyHBF₄/PC electrolyte solution is presented in Figs. 8 & 9 for various concentrations up to the 15 saturation limit of 1.62 m/l. Generally presence of a current peak on the top half or the bottom half of the graph indicates respectively an electrochemical reduction or oxidation process taking place at the potential corresponding to the peak location. In this electrolyte and electrode system there is no oxidation or reduction peak. It means that this electrolyte is stable through the voltage window indicated by the sharp rise in the current level at the end voltages. In this case 20 we see an electrochemical window of nearly 4 V. This is comparable to or higher than any known state of the art electrolyte system.

The conductivity of each solution was measured using a YSI 3200 conductivity meter. The conductivity as a function of the electrolyte concentration is shown in Table 3. Thus, the figures and the table provide evidence to this capability of the herein disclosed new electrolyte.

Table 3

Initial rest potential of the PyHBF₄/GBL electrolyte solutions and their conductivity

Concentration (M)	Rest Potential (V)	Conductivity (mS/cm)	Voltage Window (V)
5	0.25	6.6	4.00
	0.33	8.1	4.00
	0.55	11.5	4.00
	0.62	11.8	3.95
	0.75	13.7	4.00
	1.00	14.8	4.00
	1.20	16.2	3.90
	1.61	20.2	3.95

Thus, the figures and the table provide evidence to the electrochemical performance of this electrolyte at different concentrations. Even at relatively low concentrations, for example, below 1M, the electrochemical performance of the pyridinium-based salt is relatively good compared to prior art. Generally, the preferred concentration of the electrolyte for the supercapacitor application is one at which the conductivity and the electrochemical voltage window are maximum. Since the voltage window remains fairly constant at all concentrations, selecting a preferred concentration becomes a function of desired conductivity. Higher concentrations equate to higher conductivities.

What is claimed is:

1. A non-aqueous electrolyte comprising a pyridinium-based salt in a non-aqueous solvent at a concentration less than 2M.

5 2. The electrolyte of claim 1, wherein the pyridinium-based salt consists of a pyridinium cation and a perfluorinated non-metal anion.

10 3. The electrolyte of claim 2, wherein the perfluorinated non-metal anion is selected from the group consisting of perfluorinated boron, perfluorinated phosphorous, perfluorinated sulfur, perfluorinated arsenic, perfluorinated antimony, perfluoroalkylborates, perfluoroalkylphosphates, perfluoroalkylsulfonates, perfluoroalkyl-substituted imides and perfluoroalkyl-substituted methanides.

15 4. The electrolyte of claim 3, wherein the perfluorinated non-metal anion is tetrafluoroborate.

5. The electrolyte of claim 1, wherein said organic solvent is selected from the group consisting of linear ethers, cyclic ethers, esters, carbonates, formates, lactones, nitriles, dinitriles, amides, sulfones and sulfolanes.

20

6. The electrolyte of claim 5, wherein said organic solvent is selected from the group consisting of propylene carbonate, acetonitrile and gamma butyrolactone.

25 7. The electrolyte of claim 1, wherein said pyridinium-based salt is dissolved in said organic solvent at a concentration of less than 1.75 M.

8. The electrolyte of claim 1, wherein said electrolyte has a voltage window of at least 3 volts.

9. The electrolyte of claim 1, wherein said electrolyte has a voltage window of at least 3.5
5 volts.

10. The electrolyte of claim 1, wherein said electrolyte comprises an additional salt.

11. The electrolyte of claim 10, wherein said additional salt is a tetraalkylammonium or
10 tetraalkylphosphonium salt having perfluorinated anion.

12. The electrolyte of claim 10, further comprising an addition non-aqueous solvent.

13. The electrolyte of claim 1, further comprising an addition non-aqueous solvent.

15

14. An electrical energy storage device comprising a non-aqueous electrolyte comprising a pyridinium-based salt in a non-aqueous solvent at a concentration less than 2M.

15. The electrical energy storage device of claim 14, wherein said pyridinium-based salt is
20 dissolved in said organic solvent at a concentration of less than 1.75 M.

16. The electrical energy storage device of claim 14, wherein the perfluorinated non-metal anion is selected from the group consisting of PF₆⁻, AsF₆⁻, BF₄⁻.

25 17. The electrical energy storage device of claim 16, wherein the perfluorinated non-metal ion is tetrafluoroborate.

18. The electrical energy storage device of claim 14, wherein said organic solvent is selected from the group consisting of linear ethers, cyclic ethers, esters, carbonates, formates, lactones, nitriles, dinitriles, amides, sulfones and sulfolanes.

5

19. The electrical energy storage device of claim 18, wherein said electrolyte comprises a non-aqueous solvent selected from the group consisting of propylene carbonate, acetonitrile and gamma butyrolactone.

10 20. The electrical energy storage device of claim 14, further comprising carbon-based electrodes.

21. The electrical energy storage device of claim 14, wherein said electrolyte has a voltage window of at least 3 volts.

15

22. The electrical energy storage device of claim 21, wherein said electrolyte has a voltage window of at least 3.5 volts.

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Propylene Carbonate @ .51 moles/l

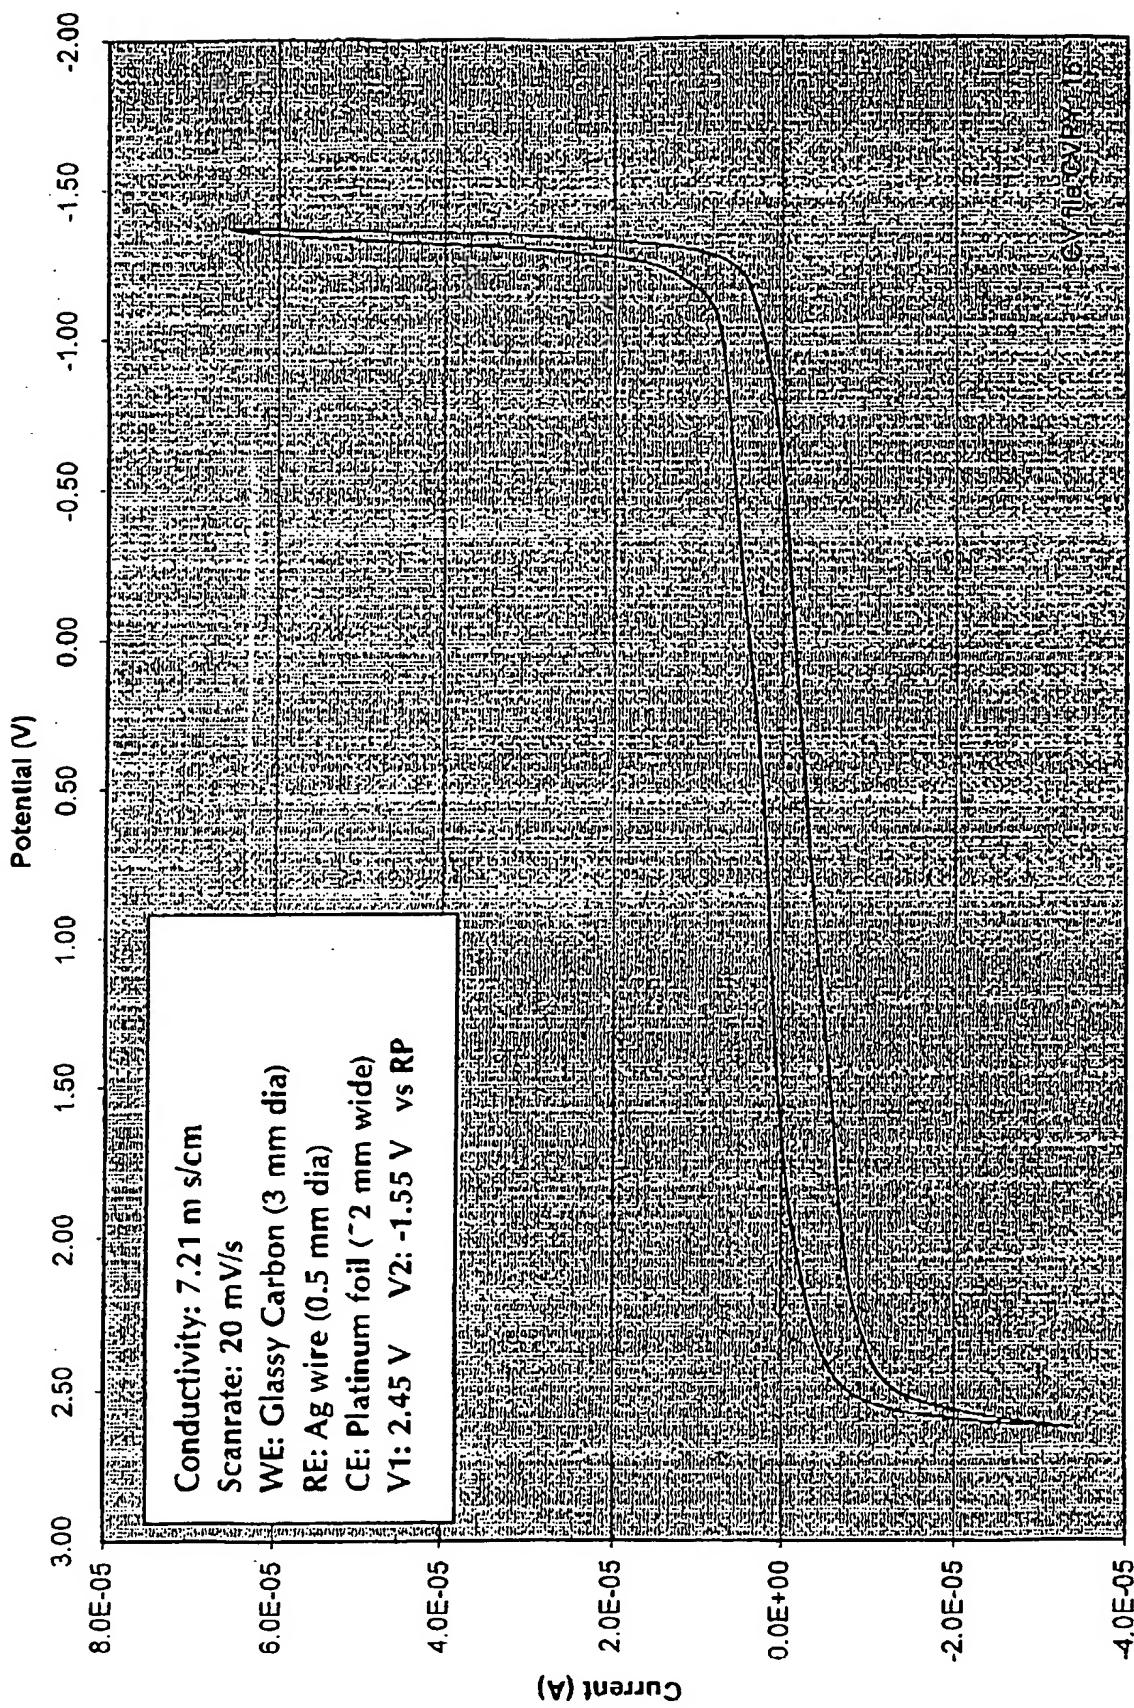

Fig. 1

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Propylene Carbonate @ .75 moles/l

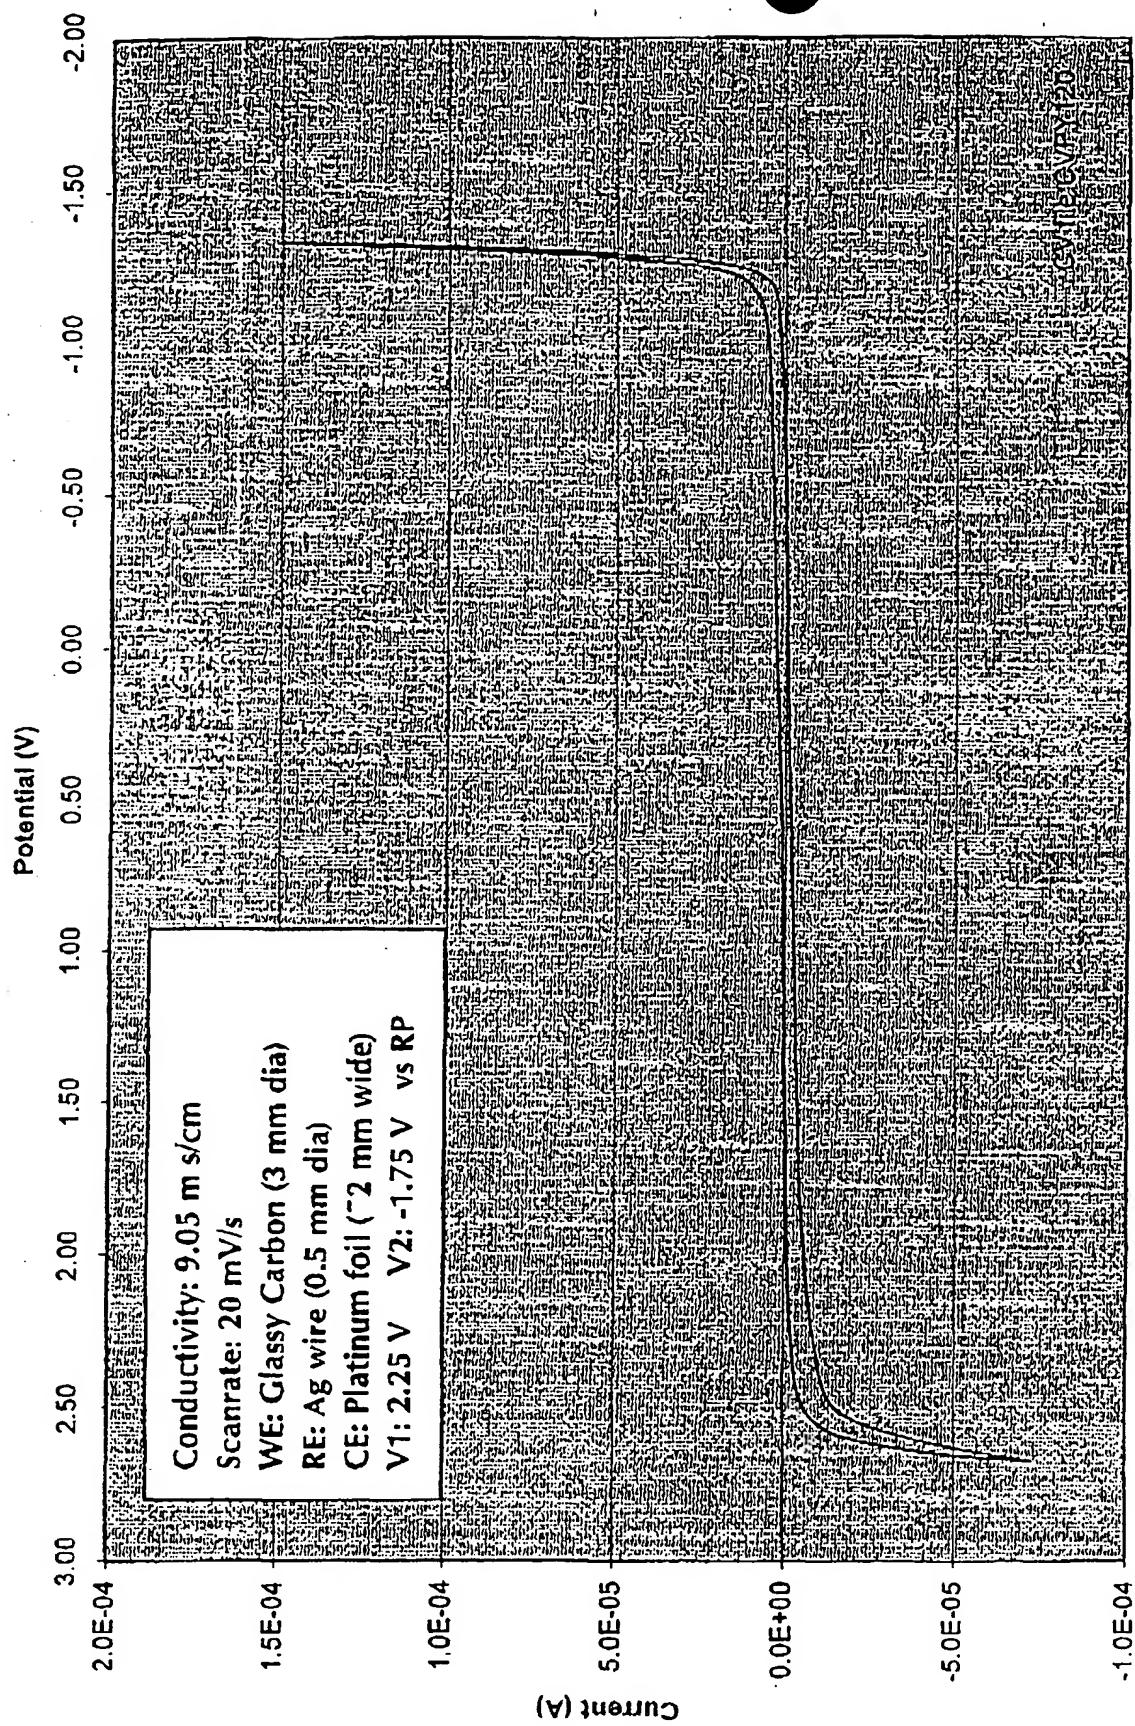

Fig. 2

Cyclic Voltammetry Pyridinium Tetrafluoroborate in Propylene Carbonate @ 1.02 moles/l

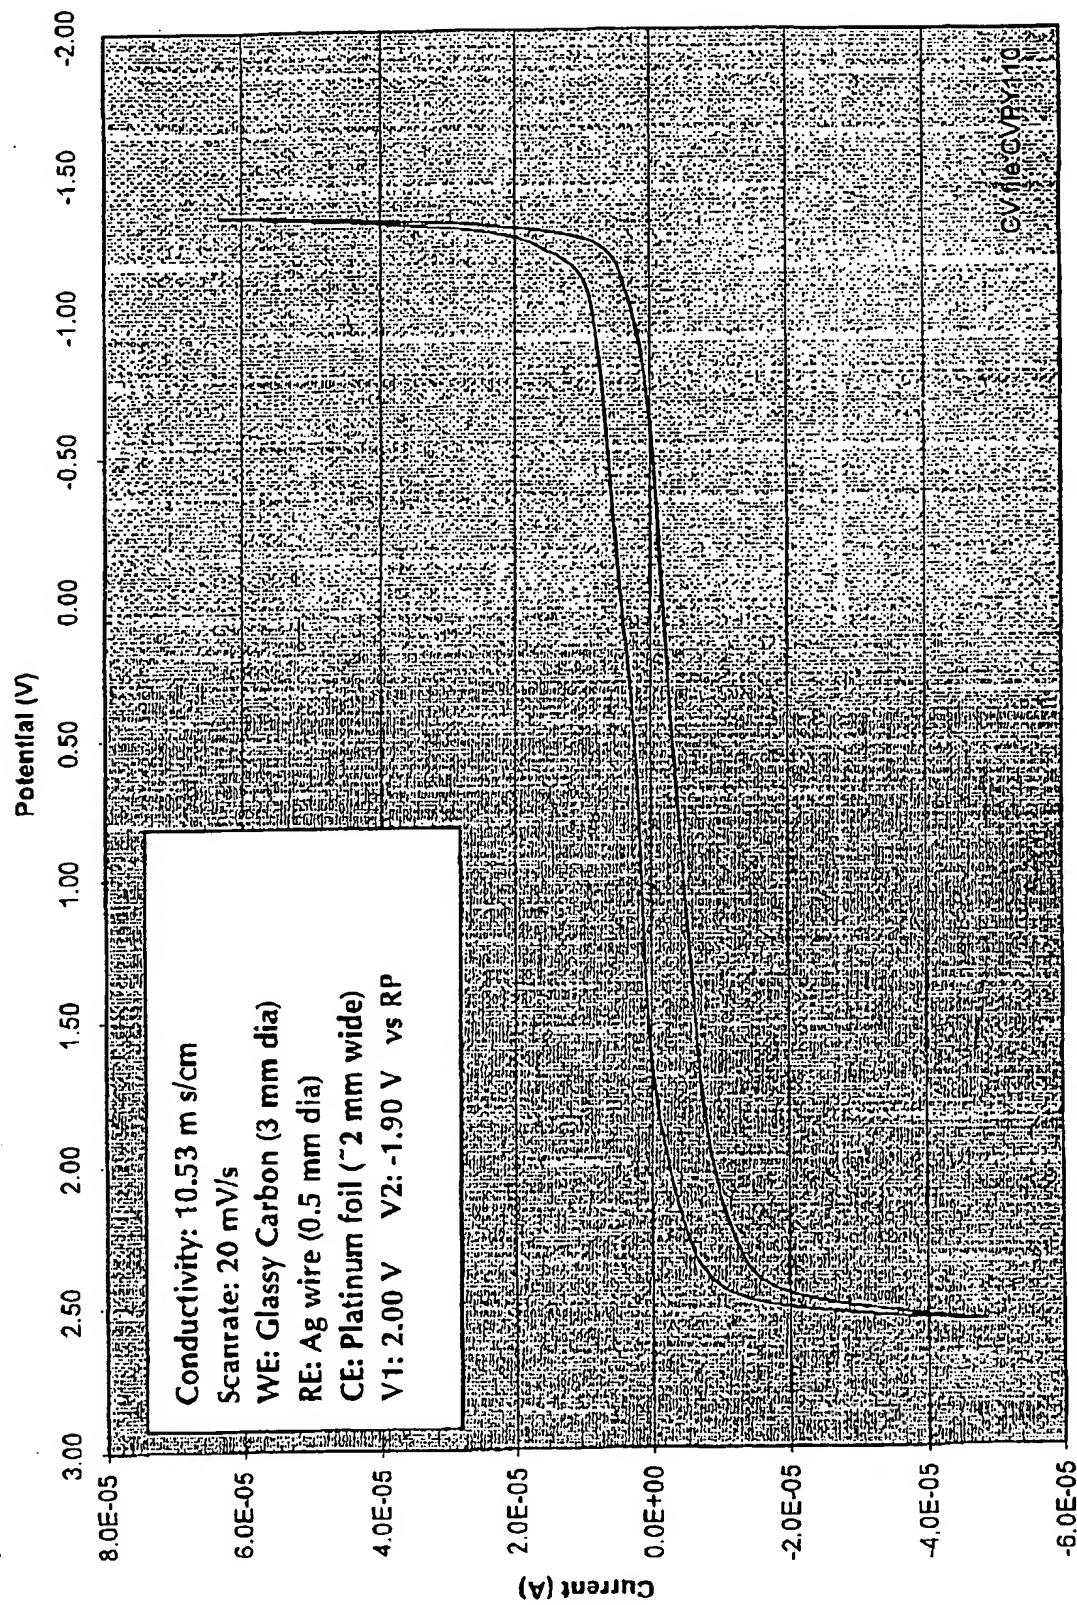

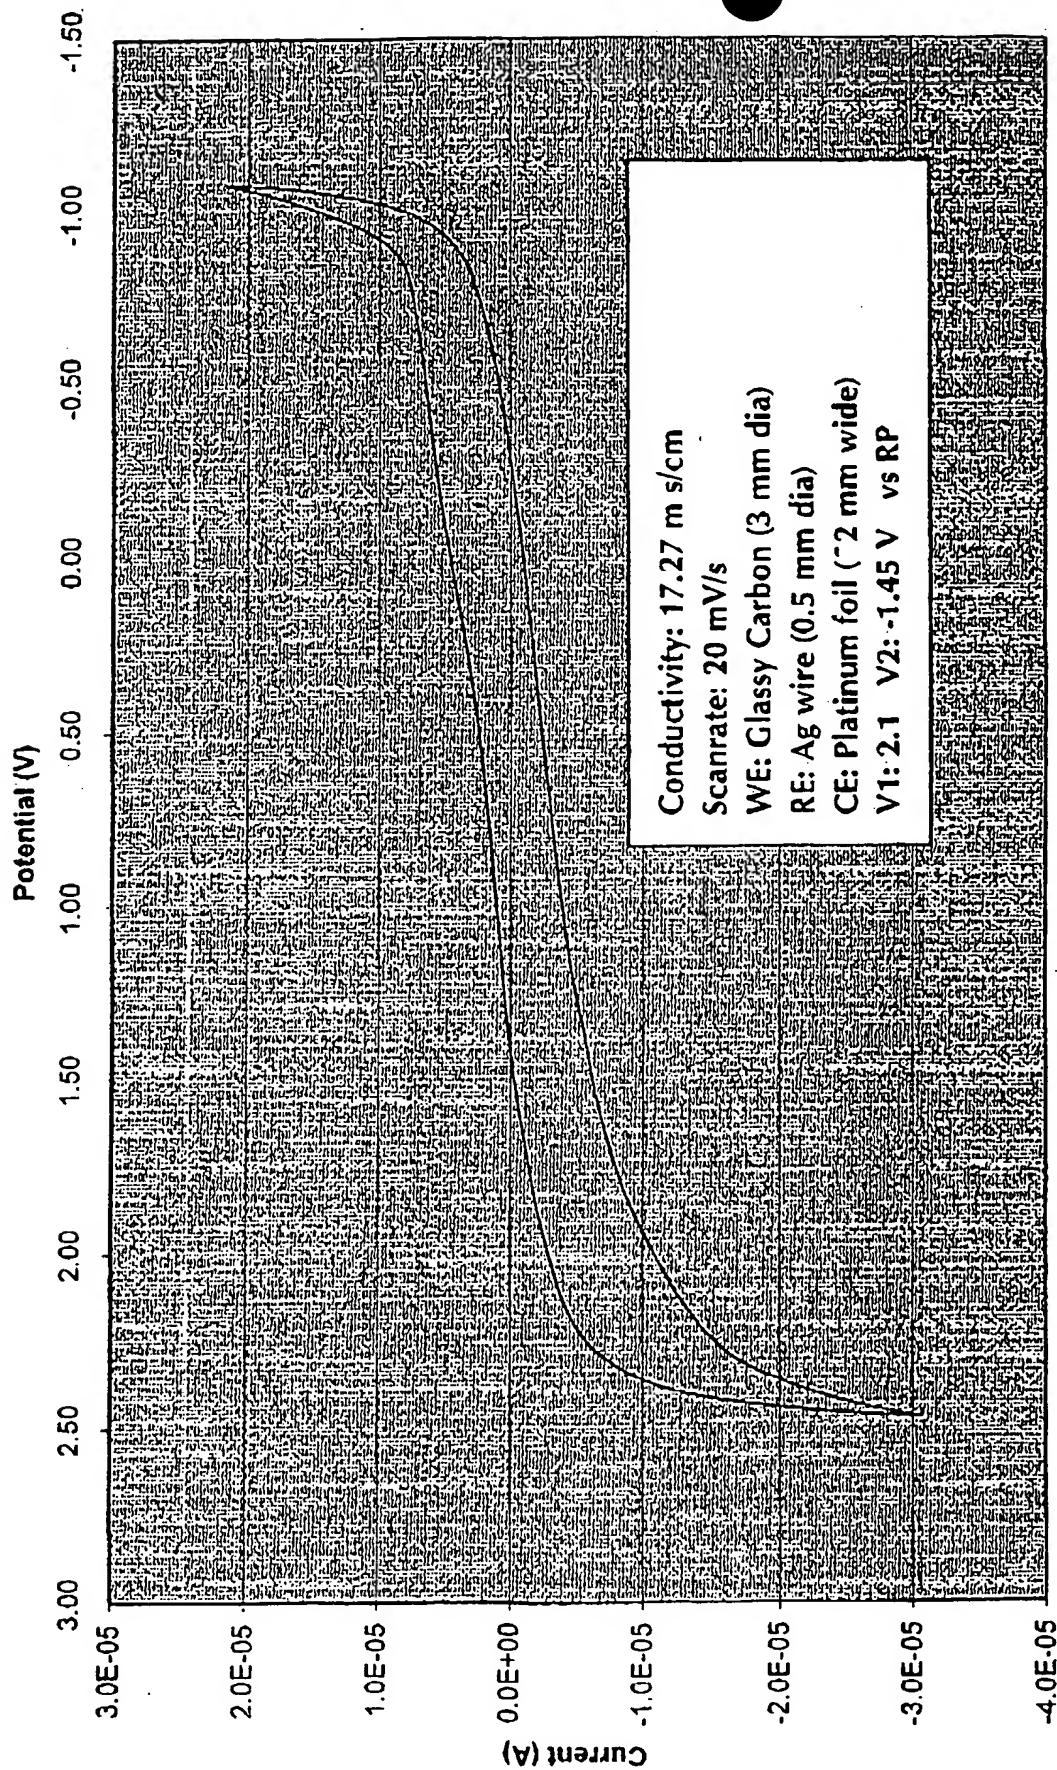

Fig 3

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Acetonitrile @ .22 moles/l

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Acetonitrile @ .33 moles/l

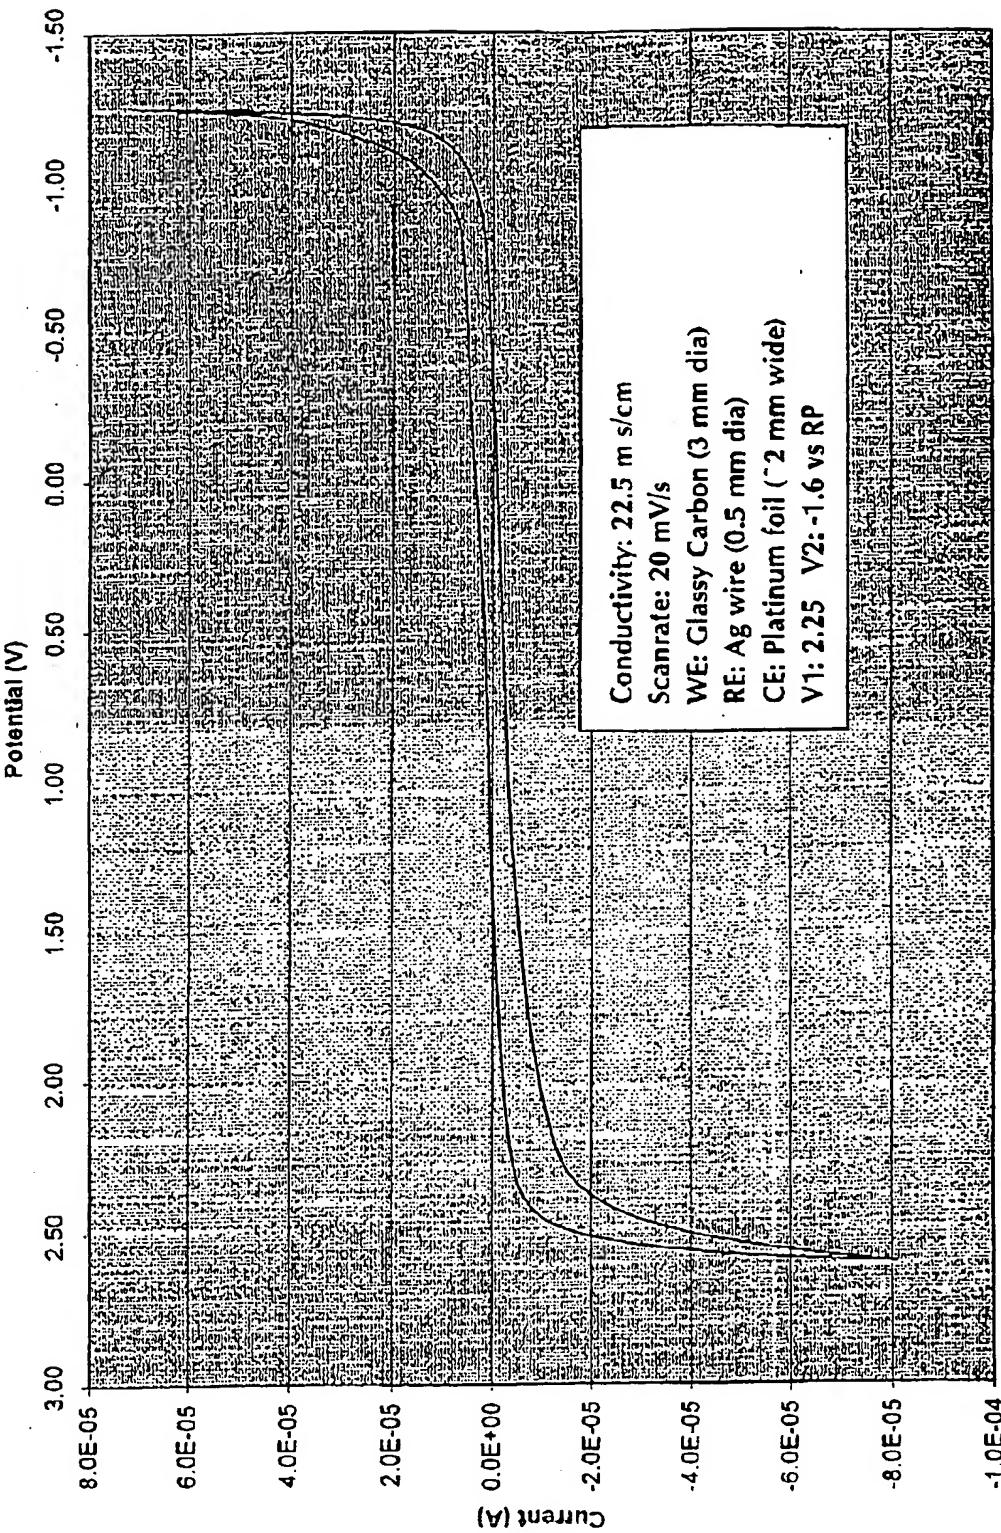

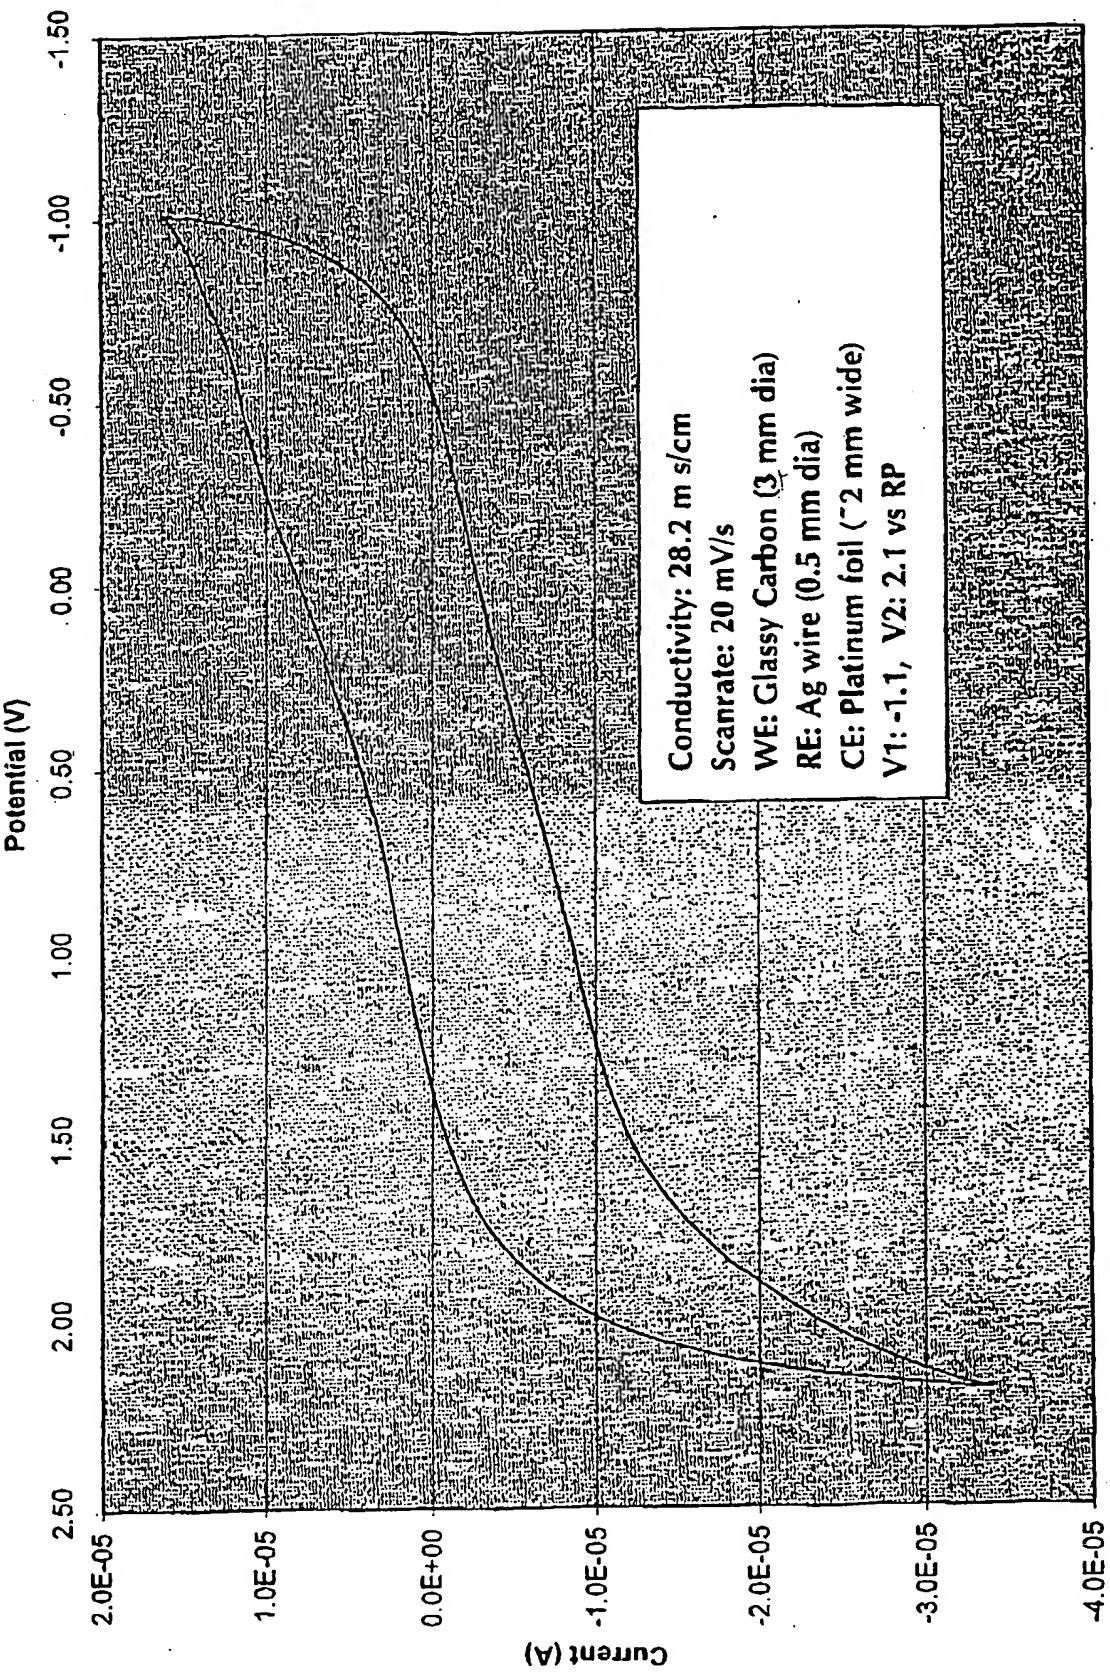

Fig. 5

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Acetonitrile @ .46 moles/l

WO 2004/062007

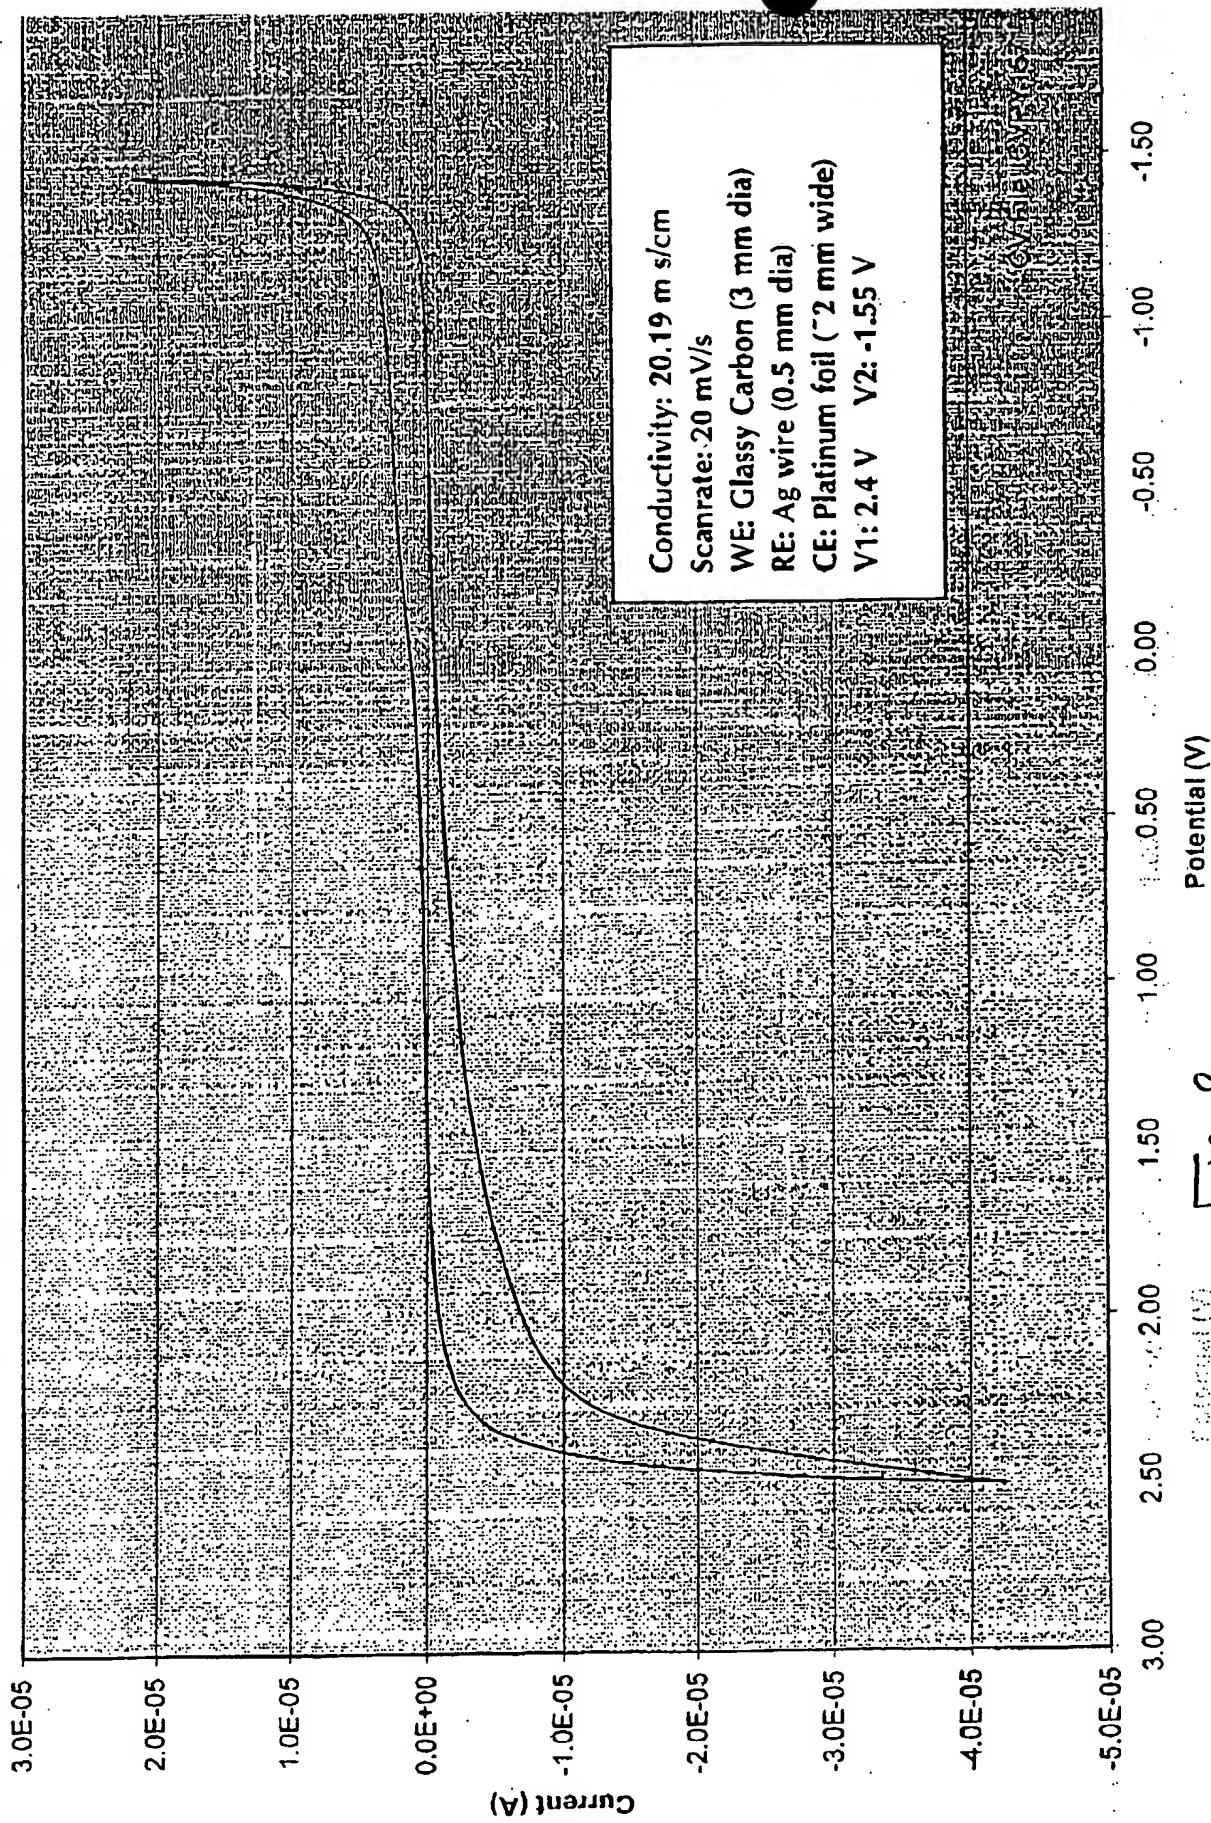

7/9

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Acetonitrile @ .59 moles/l

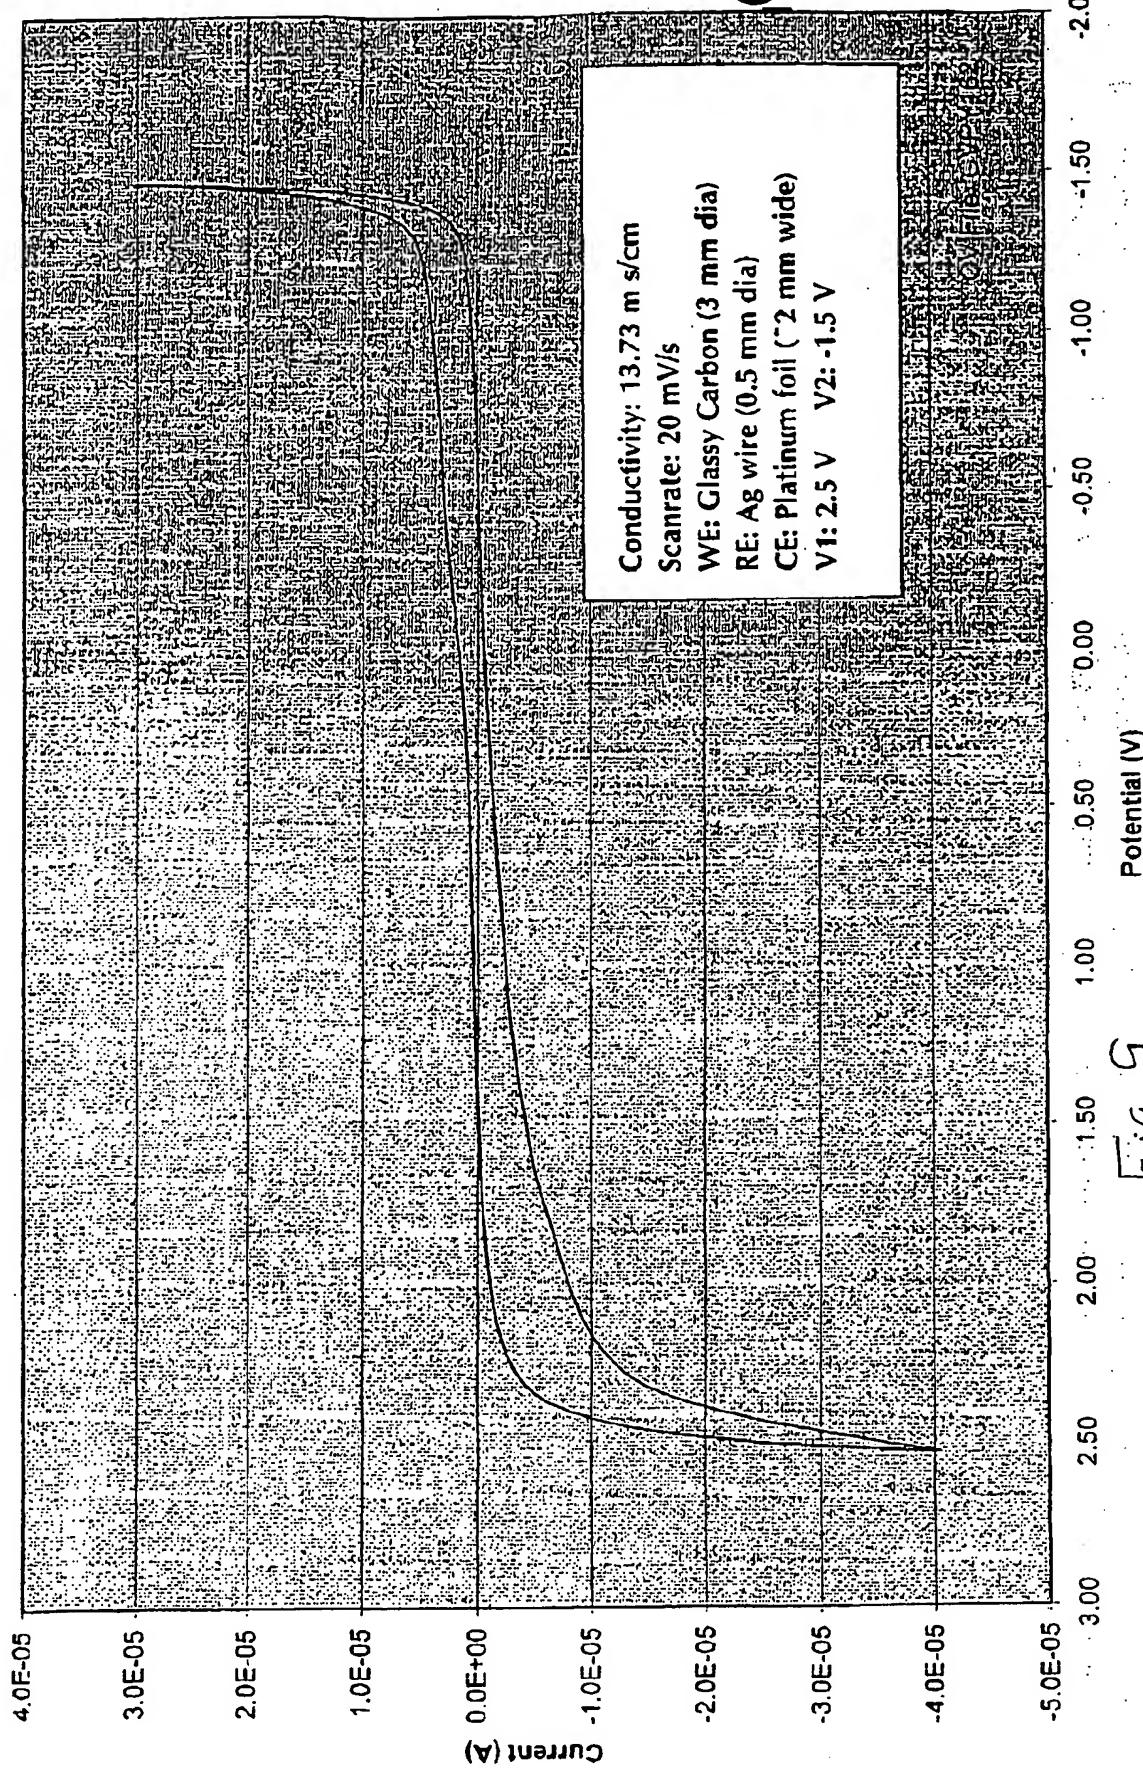

F-1 7

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Gammabutyro lactone @ ~ 1.6152 moles/l

Cyclic Voltammetry
Pyridinium Tetrafluoroborate in Gammabutyro lactone @ ~ .75 moles/l

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US03/41210

A. CLASSIFICATION OF SUBJECT MATTER

IPC(7) : H01M 6/04, 6/16
US CL : 429/188, 326, 337, 338, 339

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 429/188, 326, 337, 338, 339

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)
Derwent, search terms: pyridinium, salt, tetraalkylammonium, tetraalkylphosphonium, battery, perfluorin§

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 4,537,843 A (SHISHIKURA et al) 27 August 1985 (27.08.1985), col. 6 line 13-68, col. 7 line 19-52.	1-10; 12-22
---		----- 11
Y	US 4,882,244 A (DONAHUE et al) 21 November 1989 (21.11.1989), col. 3 line 23-35.	11

Further documents are listed in the continuation of Box C.

See patent family annex.

Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A" document defining the general state of the art which is not considered to be of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E" earlier application or patent published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&"	document member of the same patent family
"O" document referring to an oral disclosure, use, exhibition or other means		
"P" document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search
12 April 2004 (12.04.2004)

Date of mailing of the international search report

30 APR 2004

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- BLACK BORDERS**
- IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- FADED TEXT OR DRAWING**
- BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- SKEWED/SLANTED IMAGES**
- COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- GRAY SCALE DOCUMENTS**
- LINES OR MARKS ON ORIGINAL DOCUMENT**
- REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
